MECHANICAL PROPERTIES OF HASTELLOY SHEET
ALLOY R - 235 AT CRYOGENIC TEMPERATURES

MRG-300

March 19, 1962

GENERAL DYNAMICS / CONVAIR

19 March 1962

SUBJECT: Mechanical Properties of Hastelloy Sheet Alloy R-235
at Cryogenic Temperatures

ABSTRACT: Hastelloy alloy R-235 is a nickel base alloy developed for high temperature (to 1750°F) service. It was the purpose of this investigation to determine the applicability of this alloy for structural uses at cryogenic temperatures. Parent metal and welded tensile properties and toughness, as determined by notched ($K_t = 6.3$) tensile strengths and notched/unnotched tensile ratios, were evaluated at 78°, -100°, -320° and -423°F. The alloy was tested in the annealed and two aged conditions.

The data indicate that the R-235 alloy remains as tough at cryogenic temperatures (to -423°F) as it is at room temperature for the conditions tested. This alloy does have a rather low yield strength to density ratio as compared to other high strength sheet materials (e.g. 60% C.R., 301 S.S., 2014-T6 Al., Ti-5Al-2.5Sn), however may find application if service conditions range from very low (to -423°F) to quite high (1750°F) temperatures.

SUBJECT: Mechanical Properties of Hastelloy Sheet Alloy R-235
at Cryogenic Temperatures

INTRODUCTION:

There are several proposed vehicles, such as recoverable boosters, powered re-entry vehicles, etc., which require structural materials with high strengths and adequate toughness over the temperature range of -423°F to $+1600$ - 1800°F . These temperatures are encountered in service due to the proposed use of liquid oxygen (b.p. of -297°F) and liquid hydrogen (b.p. of -423°F) as propellants and due to the frictional heating during atmospheric re-entry. It was the purpose of this investigation to determine if Hastelloy R-235 alloy, which has good high temperature properties (to $+1750^{\circ}\text{F}$), may be used for structural applications at cryogenic temperatures.

R-235 is a vacuum melted nickel base alloy which contains aluminum and titanium for precipitation hardening. It is the presence of the $\text{Ni}_3(\text{Al-Ti})$ precipitates which account for the alloys high temperature strength. The alloy is readily available in many forms (sheet, plate, wire, bar, tubing and forging stock) and can be easily fabricated (machined, formed, and resistance and fusion welded). R-235 possesses good high temperature oxidation resistance, resists over-aging at elevated temperatures, and may be easily heat treated.

MATERIALS:

A sheet of 0.015 inch thick R-235 alloy was supplied by Haynes - Stellite Company to perform the test work. The chemical analysis and physical properties of this material are given in Table 1. The alloy was tested in the as-received (annealed - 2150°F , A. C.) and two aged conditions.

PROCEDURE:

Blanks for tensile specimens, $9" \times 1\frac{1}{2}"$, were identified and sheared. Panels of the alloy were inert-arc fusion welded on production equipment, identified, and sheared into tensile blanks. Some of the tensile blanks were aged in the Materials Research Group heat-treating laboratory. Two different aging treatments were employed. One group, including welded blanks, was aged at 1450°F for 24 hours and air cooled. Other specimen blanks were aged at 1600°F for 20

19 March 1962

minutes followed by air cooling. Smooth and welded specimens were machined per MRG-D-1 and notched specimens per MRG-D-10, Notch "A". Notched specimens were inspected and measured by an optical comparator. Tests were performed at 78°F (room temperature), -100°F (by immersion in a bath of a dry ice-alcohol mixture), -320°F (immersion in liquid nitrogen) and -423°F (immersion in liquid hydrogen). Strain rates were 0.001 in/in/min. until 0.2% offset yield and 0.15"/min until failure. Total elongations on smooth and welded specimens were determined over a 2" gauge length. Strain measurements were made by use of extensometers and continuous stress-strain recorders.

RESULTS AND DISCUSSION:

The tensile, weld tensile and notched tensile properties of R-235 alloy at 78, -100, -320 and -423°F are given in Tables 2 through 4. Table 2 gives the properties of the alloy in the as-received condition. There is a continuous increase in the parent metal yield and tensile strengths, weld tensile strength, and notched tensile strength with decrease in temperature from 78°F to -423°F. The yield/density (about 200,000 in lbs/lb) and strength/density (about 400,000 in lbs/lb) ratios at 78°F are quite low as compared with other high strength sheet alloys such as 60% C.R. 301 S.S., 2014-T6 aluminum and Ti-5Al-2.5 Sn which have yield/density ratios of about 600,000 in lbs/lb. Elongations of parent metal and welded specimens were nearly the same at all testing temperatures. Weld joint efficiency decreased from 96% at 78°F to 84% at -423°F. Notched tensile strengths increased at about the same rate as smooth tensile strengths with decrease in testing temperature. Therefore, notched/unnotched tensile ratios remained about the same from 78° to -423°F. The notched/unnotched tensile strength ratios were quite low, from 0.77 to 0.85. It is not presently understood why the annealed or solution treated conditions of certain nickel and aluminum base alloys have lower notched/unnotched tensile strength ratios than do the aged conditions of the same alloys. This type of behavior has been noted before in Rame' 41 and 2024 Al. (Ref. Reports MRG-164 and -190). However, the notched test data indicate that the annealed material is as tough at cryogenic temperatures as it is at room temperature.

Table 3 gives the data obtained on the R-235 alloy in the 1450°F, 24 hr. A.C. aged condition and Table 4 give the data on the 1600°F, 20 min., A.C. aged material. These two aging treatments are recommended for this sheet R-235 alloy. The yield, tensile, weld tensile and notched tensile strengths increase with decrease in testing temperature. Joint efficiencies are nearly 100% at all testing temperatures. Notched/unnotched tensile strength ratios increase with decrease in temperature indicating that the resistance to brittle fracture at cryogenic temperatures is as great as or greater than at room temperature. The yield and tensile strength of the 1450°F aged material

19 March 1962

are 5-10% higher than for the material aged at 1600°F.

Based on the data obtained in the present investigation it is believed that R-235 sheet alloy retains adequate toughness for structural applications at cryogenic temperatures (to -423°F) in either the annealed or aged (1450°F or 1600°F) conditions. Because of the low strength/density ratio, the R-235 alloy would probably be limited to only those applications where service conditions would range from very low (e.g. -423°F) to quite high (1750°F) temperatures.
